### Abstract

In this study, tungsten-bronze type materials of  $\text{Sr}_2\text{Sm}_{(1-x)}\text{Nd}_x\text{Ti}_2\text{Nb}_3\text{O}_{15}$  composition ( $x=0; 0,25; 0,5; 0,75$  and  $1$ ) were elaborated by classical solid-state reaction. The structural characterization demonstrate that these compounds present tetragonal symmetry, using two space groups  $P4bm$  ( $N^\circ 100$ ) and  $P4/mbm$  ( $N^\circ 127$ ) respectively. The lattice parameters are  $a = b \approx 12,2 \text{ \AA}$ ;  $c \approx 3,8 \text{ \AA}$ ;  $V \approx 579,0 \text{ \AA}^3$  and  $Z=2$ . In this compounds, Ti and Nb cations show obvious off-center displacements along the  $c$  axis in both the  $\text{Ti/Nb}(1)\text{O}_6$  and the  $\text{Ti/Nb}(2)\text{O}_6$  octahedra. Besides, the unequal  $\text{Ti/Nb}(2)-\text{O}$  bonds length in the equatorial plane of  $\text{Ti/Nb}(2)\text{O}_6$  octahedra indicates the displacement of the  $\text{Ti/Nb}(2)$  cations in the  $ab$  plane, and no displacement of the  $\text{Ti/Nb}(1)$  cations exists in the  $ab$  plane. The results show that this material has two types of octahedral, first octahedron with little deformation around the  $\text{Ti}1/\text{Nb}1$  and the second octahedron are more distorted around the  $\text{Ti}2/\text{Nb}2$ . The measurements of permittivity and dielectric losses of the ceramic samples performed between  $25^\circ\text{C}$  and  $700^\circ\text{C}$  ( $100\text{Hz}$  to  $1\text{MHz}$ ), high dielectric constants ( $\epsilon_r=127 \sim 194$ ) and low dielectric losses ( $\tan(\delta)$  around  $10^{-4}$  at  $1\text{MHz}$ ) were found. The maximum value of the dielectric constant is obtained for  $x=0$  ( $\epsilon_r=194$ ). The Curie temperature  $T_c$  decreases from  $332$  to  $246^\circ\text{C}$  as a function of the substitution of the samarium by neodymium. Detailed microstructural analysis by scanning electron microscope (SEM) and (EDS) for this compounds are also investigated.

Keywords: Tetragonal tungsten bronze, crystalline structure, X-ray diffraction, dielectric properties.

### 1 - Introduction

Interesting dielectric properties and for some of them ferroelectric/piezoelectric properties, the tetragonal tungsten bronze materials (TTB) are used for varied applications in the field of microelectronic and microelectromechanical devices, such as capacitors or actuators and they attracted an increasing scientific interest [1-8]. Most of the dielectric applications are based on three criteria: high relative permittivity ( $\epsilon_r$ ), low values of dielectric loss ( $\tan\delta$ ), and a coefficient of temperature ( $\tau_e$ ) which must be nearest as possible of  $0\text{ppm}/^\circ\text{C}$ . The TTB are used in microelectronic devices since they fulfil some of these criteria. The TTB structure consists mainly of a complex array of distorted  $\text{BO}_6$  octahedra sharing corners in the three directions of the space, what lets appear three different types of interstices: square tunnels (A1), pentagonal tunnels (A2) and triangular tunnels (C) which allows a large chemical flexibility and generates a significant number of possible compositions [9]. The general formula of TTB is  $(\text{A}1)_2(\text{A}2)_4(\text{C})_4(\text{B}1)_2(\text{B}2)_8\text{O}_{30}$  [10-14]. In this formula, the (A1) and (A2) sites are occupied by large monovalent ions ( $\text{Na}^+$ ,  $\text{K}^+$ ...), divalent ions ( $\text{Sr}^{2+}$ ,  $\text{Ba}^{2+}$ ...) or trivalent ions ( $\text{Sm}^{3+}$ ,  $\text{Bi}^{3+}$ ...). The triangular channels (C) can only contain relatively small ions such as  $\text{Li}^+$  and are often empty. The (B1) and (B2) octahedral sites contains small and highly charged ions such as  $\text{Nb}^{4+}$  or  $\text{Ti}^{4+}$  [13, 15, 16]. The dielectric ceramics of TTB-type belonging to the quaternary system  $\text{AO-Ln}_2\text{O}_3-\text{TiO}_2-\text{M}_2\text{O}_5$  ( $\text{A}=\text{Ba}$ ,  $\text{Sr}$ .  $\text{Ln}=\text{Sm}$ ,  $\text{Nd}$  and  $\text{M}=\text{Y}$ ,  $\text{Nb}$ ), have already been studied by several authors [17-21]. Among these compositions, materials such as  $\text{Ba}_3\text{La}_3\text{Ti}_5\text{Ta}_5\text{O}_{30}$ ;  $\text{Ba}_4\text{La}_2\text{Ti}_4\text{Ta}_6\text{O}_{30}$ ;  $\text{Ba}_5\text{LaTi}_3\text{Ta}_7\text{O}_{30}$ ; present a high dielectric constant ( $\epsilon_r=127,7 - 148$ ), low dielectric losses ( $\tan(\delta)=10^{-4} - 10^{-3}$  at  $1\text{MHz}$ ), and a relatively high temperature coefficient ( $\tau_e=-728$  to  $-1347 \text{ ppm}/^\circ\text{C}$ ) [22]. The compounds  $\text{Ba}_2\text{NdTi}_2\text{Ta}_3\text{O}_{15}$ ;  $\text{Ba}_3\text{Nd}_3\text{Ti}_5\text{Ta}_5\text{O}_{30}$  and  $\text{Ba}_5\text{NdTi}_3\text{Ta}_7\text{O}_{30}$  has also been prepared and present interesting relative permittivity ( $\epsilon_r=103,1 - 171,7$ ) [4]. Furthermore. H. ZHANG et al [23], evidenced for the niobates  $\text{Sr}_4\text{R}_2\text{Ti}_4\text{Nb}_6\text{O}_{30}$  ( $\text{R}=\text{Sm}$  and  $\text{Nd}$ ), i.e.  $\text{Sr}_4\text{Nd}_2\text{Ti}_4\text{Nb}_6\text{O}_{30}$  (SNTN) and  $\text{Sr}_4\text{Sm}_2\text{Ti}_4\text{Nb}_6\text{O}_{30}$  (SSTN). The Curie temperature of these compounds are  $260$  and  $370^\circ\text{C}$  for SNTN and SSTN, respectively. Other compositions such as  $\text{Sr}_4\text{La}_2\text{Ti}_4\text{M}_6\text{O}_{30}$  ( $\text{M}=\text{Nb}$ ,  $\text{Ta}$ ) [24],  $\text{Sr}_5\text{RTi}_3\text{Nb}_7\text{O}_{30}$  ( $\text{R}=\text{Gd}$ ,  $\text{Dy}$ ) [25],  $\text{Sr}_5\text{SmTi}_3\text{Nb}_7\text{O}_{30}$  and  $\text{Sr}_4\text{Sm}_2\text{Ti}_4\text{Nb}_6\text{O}_{30}$  [26] have also been evidenced. In particular, we have noticed that the structural study of  $\text{Sr}_2\text{LnTi}_2\text{Nb}_3\text{O}_{15}$  compounds ( $\text{Ln}$ : rare earth) and their solid solutions has not been performed at the present time. Thus, the aim of this work is to study the solid solution  $\text{Sr}_2\text{Sm}_{(1-x)}\text{Nd}_x\text{Ti}_2\text{Nb}_3\text{O}_{15}$  ( $0 \leq x \leq 1$ ) in order to: (i) check for the occurrence of the  $\text{Sr}_2\text{SmTi}_2\text{Nb}_3\text{O}_{15}$  and  $\text{Sr}_2\text{NdTi}_2\text{Nb}_3\text{O}_{15}$  compounds, (ii) establish the structural evolution in the solid solution, (iii) to study their electrical properties and (iv) to establish relationships between the crystalline structure and the dielectric properties.

## 2. Materials and methods

### 2.1 Synthesis and sintering

The  $\text{Sr}_2\text{Sm}_{(1-x)}\text{Nd}_x\text{Ti}_2\text{Nb}_3\text{O}_{15}$  compositions  $\text{Sr}_2\text{SmTi}_2\text{Nb}_3\text{O}_{15}$ ;  $\text{Sr}_2\text{Sm}_{0.75}\text{Nd}_{0.25}\text{Ti}_2\text{Nb}_3\text{O}_{15}$ ;  $\text{Sr}_2\text{Sm}_{0.5}\text{Nd}_{0.5}\text{Ti}_2\text{Nb}_3\text{O}_{15}$ ;  $\text{Sr}_2\text{Sm}_{0.25}\text{Nd}_{0.75}\text{Ti}_2\text{Nb}_3\text{O}_{15}$  and  $\text{Sr}_2\text{NdTi}_2\text{Nb}_3\text{O}_{15}$ ; were prepared by a conventional solid-state reaction method. The chemical reaction for the synthesis is:

The starting materials were high purity  $\text{SrCO}_3$  (99,95%, Aldrich),  $\text{Nd}_2\text{O}_3$  (99,99%, Sigma-Aldrich),  $\text{Sm}_2\text{O}_3$  (99,99%, Aldrich),  $\text{TiO}_2$  (99,99%, Aldrich), and  $\text{Nb}_2\text{O}_5$  (99,99%, Aldrich). Before use,  $\text{Sm}_2\text{O}_3$  and  $\text{Nd}_2\text{O}_3$  were dried at 800°C for 30 minutes in order to remove any water and carbon dioxide. The starting powders were weighed according to the ground in an agate mortar in order to homogenize the powder and to decrease the grain size. The mixtures were calcined in alumina crucibles at 1350°C for 12 hours in air, with a heating and a cooling rate of 5°C/min.

After synthesis, the powders were ground and pressed at 98MPa in order to obtain some cylindrical pellets of 12mm in diameter and approximately 2mm in thickness. These disks were sintered at 1350°C and 1400°C in air for 2h (5°C/min) in order to obtain ceramics with relative density higher than 90%.

### 2.2 X-ray diffraction (XRD)

The crystal structure and structural evolution was studied by powder X-Ray diffraction (XRD, Bruker D8) using  $\text{Cu K}\alpha_1$  radiation ( $\lambda=1,5406\text{\AA}$ ) at room temperature. The XRD patterns were recorded for  $5^\circ \leq 2\theta \leq 120^\circ$  with a step width of  $0,02^\circ$ . The Fullprof [27] and Jana 2006 software [28] were used to perform Rietveld refinement of the XRD patterns [29].

### 2.3 Dielectric measurements

Before dielectric characterization, the experimental density of the ceramic samples was determined by Archimedes' method. For the dielectric measurements, the ceramic pellets were electroded on both sides using silver paste paint, which was fired in air at 700°C for 30min. The relative permittivity and dielectric losses  $\tan(\delta)$  were determined using an impedance analyzer (HP 4194A) in a broad frequency range (100Hz – 1MHz) and for various temperatures (20°C – 800°C), using a 5°C/min heating and cooling rate.

### 2.4 Scanning Electron Microscopy SEM and EDX analysis

The microstructure of the ceramic samples was studied by SEM (SEM Stereoscan S260, Cambridge Instruments). Chemical analysis was also performed by Energy Dispersive X-Ray Spectroscopy (EDX) in order to check for the correct stoichiometry of the ceramic samples.

## 3. Results and discussion

### 3.1 Considerations concerning the stability of the TTB structure

The stability of the TTB structure such as the solid solution  $\text{Sr}_2\text{Sm}_{(1-x)}\text{Nd}_x\text{Ti}_2\text{Nb}_3\text{O}_{15}$  is linked to the structural parameters. It must comply with conditions such as geometry, the electronegativity, electro neutrality.

#### 3.1.1 Geometrical conditions

The tolerance factor ( $t_A$ ) for TTB structure has been discussed by Wakiya et al [30]. This parameter allows to estimate the stability of the crystal structure [31, 32] when the value of ( $t_A$ ) is higher than 0,95; Thus, the value of  $t_A$  can be calculated for the two sites based on geometrical considerations by the following equations:

$$t_{A1} = \frac{r_{A1} + r_O}{\sqrt{2}(r_B + r_O)} \quad (1)$$

$$t_{A2} = \frac{r_{A2} + r_O}{\sqrt{23+12\sqrt{3}}(r_B + r_O)} \quad (2)$$

Where  $t_{A1}$  and  $t_{A2}$  represent the tolerance factor of (A1) and (A2) sites respectively,  $r_A$ ,  $r_B$  and  $r_O$  are the ionic radii of the ions for (A) sites, (B) sites, and oxygen ion, respectively  $r(\text{Sr}^{2+})=1,44\text{\AA}$  12-CN;  $r(\text{Sm}^{3+})=1,24\text{\AA}$ ; 12-CN;  $r(\text{Nd}^{3+})=1,27\text{\AA}$ ; 12-CN;  $r(\text{Ti}^{4+})=0,605\text{\AA}$ ; 6-CN;  $r(\text{Nb}^{5+})=0,64\text{\AA}$ ; 6-CN given by Shannon and Prewitt [33]. The tolerance factor ( $t_A$ ) for the TTB structure is calculated using a combination of  $t_{A1}$  and  $t_{A2}$ :

$$t_A = \frac{t_{A1} + 2t_{A2}}{3} \quad (3)$$

The stable compounds of TTB structure have a tolerance factor of close to 1. In the case of the  $\text{Sr}_2\text{Sm}_{(1-x)}\text{Nd}_x\text{Ti}_2\text{Nb}_3\text{O}_{15}$  solid solution, the ( $t_A$ ) values ranges from 0,9350 ( $x=0$ ) to 0,9385 ( $x=1$ ) indicating probably stable TTB structures (fig. 1).

### 3.1.2 Condition of electronegativity

The electronegativity difference between A and B ions and oxygen ion is another important parameter for assessing the stability of the structure [31, 32]. The more important is this difference, the more stable is the structure. The relative stability can be estimated using the following equation based on electronegativities :

$$e = \frac{(\chi_A - \chi_O) + (\chi_B - \chi_O)}{2} \quad (4)$$

Where  $(\chi_A - \chi_O)$  and  $(\chi_B - \chi_O)$  are the electronegativity difference between (A\_O) and (B\_O) respectively. In the case of the  $\text{Sr}_2\text{Sm}_{(1-x)}\text{Nd}_x\text{Ti}_2\text{Nb}_3\text{O}_{15}$  solid solution, the effect of electronegativities can be calculated by the following equation:

$$e = \frac{2(\chi_{\text{Sr}} - \chi_{\text{O}}) + (1-x)(\chi_{\text{Sm}} - \chi_{\text{O}}) + x(\chi_{\text{Nd}} - \chi_{\text{O}}) + 2(\chi_{\text{Ti}} - \chi_{\text{O}}) + 3(\chi_{\text{Nb}} - \chi_{\text{O}})}{8} \quad (5)$$

The electronegativity of the chemical being 0,95 for Sr; 1,17 for Sm; 1,14 for Nd; 1,54 for Ti; 1,6 for Nb and 3,44 for O [34]. The calculation presents an increase of the "e" factor and thus an increase of the stability of the structure with the increasing values of x (Fig. 1.).

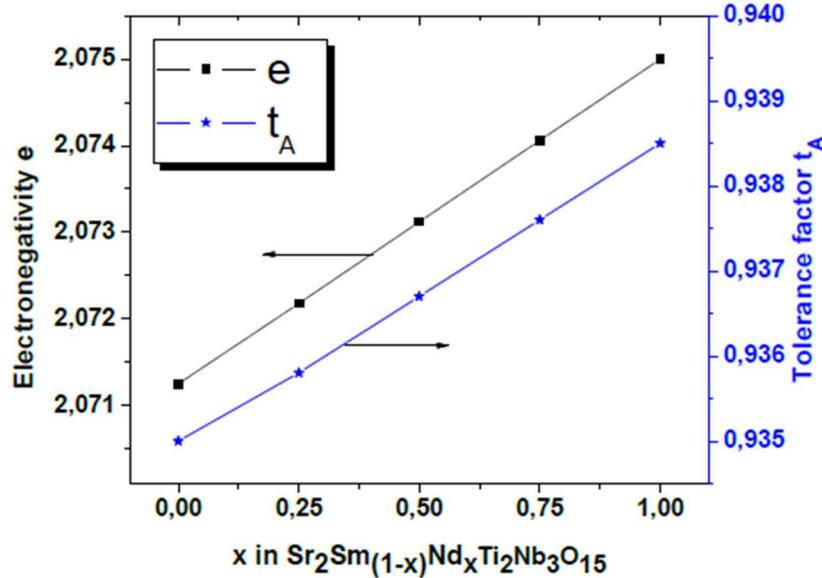

Fig. 1: Variation of the electronegativity criteria (e) and tolerance factor ( $t_A$ ) for the  $\text{Sr}_2\text{Sm}_{(1-x)}\text{Nd}_x\text{Ti}_2\text{Nb}_3\text{O}_{15}$  solid solution.

### 3.2 Structural study by X-ray diffraction

The XRD patterns for  $\text{Sr}_2\text{Sm}_{(1-x)}\text{Nd}_x\text{Ti}_2\text{Nb}_3\text{O}_{15}$  powders ( $x=0; 0,25; 0,5; 0,75$  and  $1$ ) are represented fig.3. All of them are indexed as tetragonal tungsten bronze structure, unit cell  $a=b=12,22476 \text{ \AA}$  and  $c=3,85 \text{ \AA}$ . Refinement of XRD data was carried out using the basic TTB structure [35] and [36] as a starting models with the two space groups, P4bm and P4/mbm respectively. The final differences and profile fits are shown in Fig. 2. Nearly all peaks are indexed, with the exception of one very weak peak low intensity. Refinement in P4bm gave a much better fit than that in P4/mbm, with lower R factors (Table.1), and was adopted as the preferred model.

Rietveld refinement was performed for each pattern. As an example of such result, the final differences and profile fits for  $\text{Sr}_2\text{SmTi}_2\text{Nb}_3\text{O}_{15}$  and  $\text{Sr}_2\text{NdTi}_2\text{Nb}_3\text{O}_{15}$  are shown in Fig. 3.

#### 3.2.1 Evolution of lattice parameters

The evolution of the "a" and "c" lattice parameters and unit cell volume "V" is represented Fig. 4. When substituting Nd for Sm, the "c" value increase, while the value of the "a" lattice parameter increase together with the lattice volume "V". This increase is logical since the ionic radius of neodymium ( $R_{\text{Nd}^{3+}}=1,27 \text{ \AA}$ ) is higher than the one of samarium ion ( $R_{\text{Sm}^{3+}}=1,24 \text{ \AA}$ ).

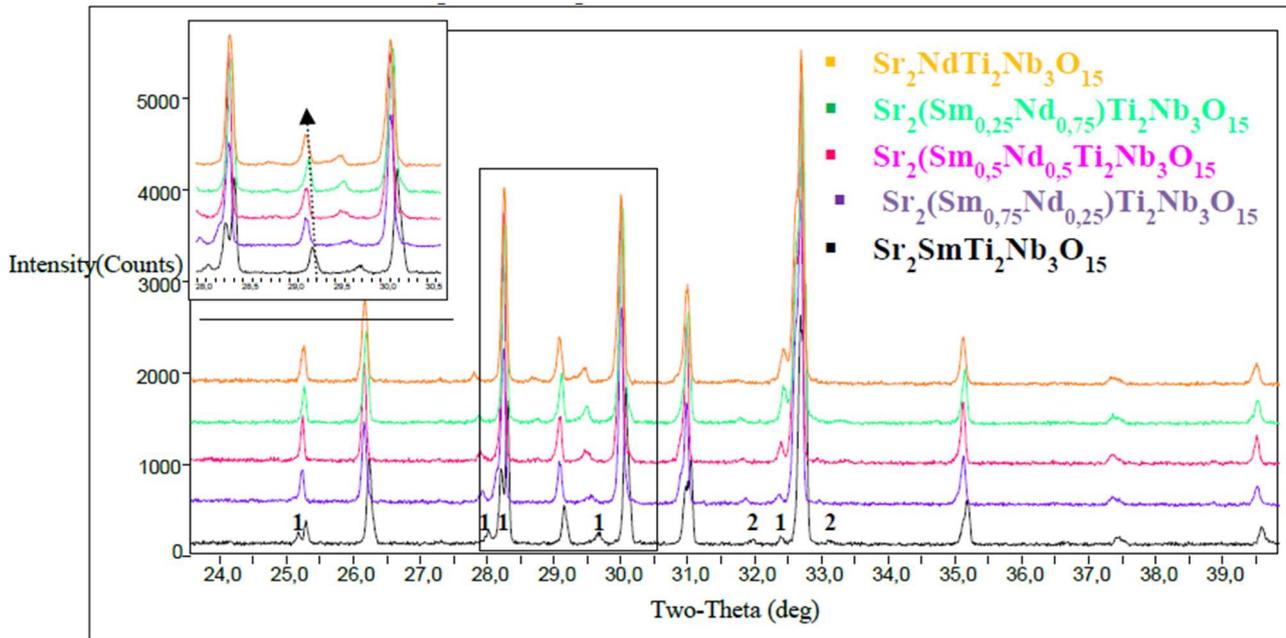

Fig. 2 : XRD patterns of solid solution  $\text{Sr}_2\text{Sm}_{(1-x)}\text{Nd}_x\text{Ti}_2\text{Nb}_3\text{O}_{15}$  ( $0 \leq x \leq 1$ ) at room temperature. 1 Minor amount of  $\text{Nb}_2\text{O}_5$  and 2  $\text{SmNbO}_4$  secondary phases is detected.

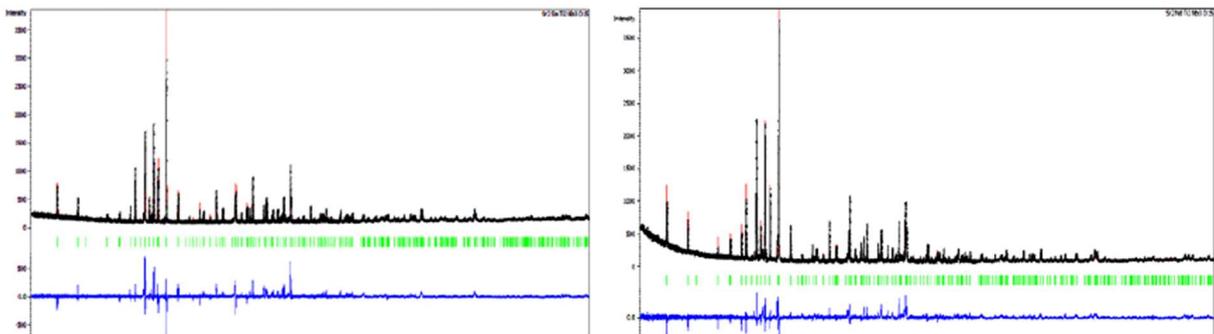

Fig. 3 : Rietveld structural refinement result for  $\text{Sr}_2\text{SmTi}_2\text{Nb}_3\text{O}_{15}$  (left) and  $\text{Sr}_2\text{NdTi}_2\text{Nb}_3\text{O}_{15}$  (right).

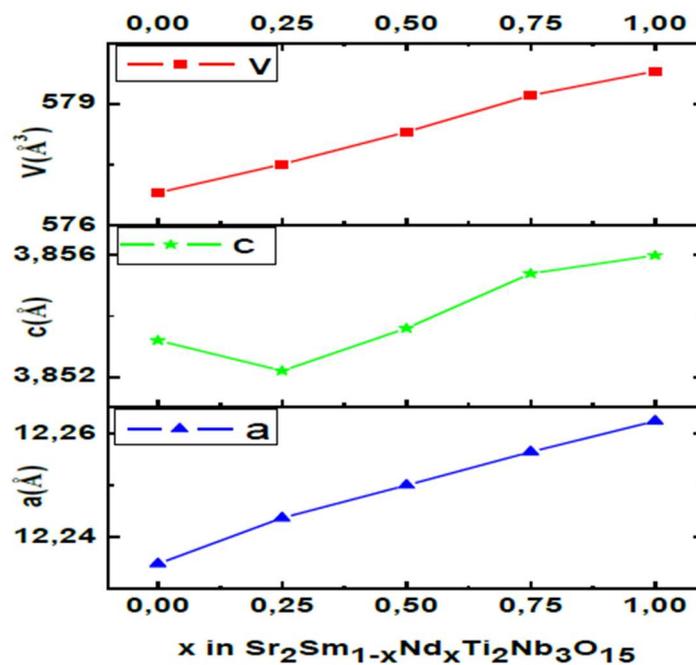

Fig. 4 : Evolution of the lattice parameters and unit cell volume as a function of the composition for the solid solution  $\text{Sr}_2\text{Sm}_{(1-x)}\text{Nd}_x\text{Ti}_2\text{Nb}_3\text{O}_{15}$  ( $0 \leq x \leq 1$ ) at room temperature.

### 3.2.2 Evolution of $\frac{c}{a}\sqrt{10}$ value and octahedra distortion

According to R.J. Xie and al [37], the calculation of value of the tetragonal distortion allows to check if the octahedra undergo a distortion or not. Indeed when the value of is lower than 1, there is a distortion of the BO<sub>6</sub> octahedra. On the contrary, when this value is equal to 1, there is no distortion. For the Sr<sub>2</sub>Sm<sub>(1-x)</sub>Nd<sub>x</sub>Ti<sub>2</sub>Nb<sub>3</sub>O<sub>15</sub> solid solution, the calculated values are lower than unity (fig. 5) indicating a distortion of the BO<sub>6</sub> octahedra.

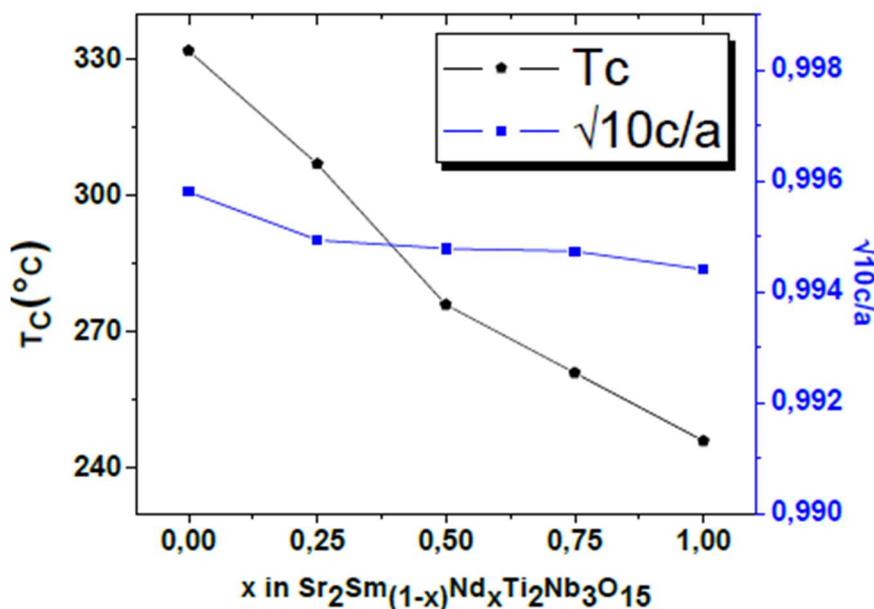

Fig. 5 : Evolution of  $\frac{c}{a}\sqrt{10}$  and T<sub>c</sub> according to the composition for the solid solution Sr<sub>2</sub>Sm<sub>(1-x)</sub>Nd<sub>x</sub>Ti<sub>2</sub>Nb<sub>3</sub>O<sub>15</sub> (0 ≤ x ≤ 1)

### 3.3 Structural study by Rietveld refinement

The refinement has been led with the P4bm space group (no centrosymmetric). The values of the confidence factors, indicative of the quality of the refinement [38], are  $8 \leq R_p \leq 11$  and  $12 \leq wRp \leq 15$  (table. 1). These values are acceptable for a refinement performed by XRD on polycrystalline samples. The profile parameters, the atomic positions and the isotropic atomic displacement parameters of the atoms were also refined. The results as a function of composition are given table. 2. The sites square (A1) (the perovskite site) are occupied by the cations of neodymium. When x increases, the (A2) sites are filled with strontium at the same time, and the atoms of titanium and niobium in sites octahedral, the (C) sites remain empty. Our samples perfectly index themselves in the quadratic system. Can the weak increase of the stitch parameters with x be explained by the weak difference of the rays of the two pressed Sm<sup>3+</sup> and Nd<sup>2+</sup> (Δr=0,03 Å).

Substitution of samarium by neodymium in the square sites leads we have noticed: Two kinds of octahedral, the first octahedral Ti/Nb(1)O<sub>6</sub> is less distorted dTi/Nb(1)-O(4) the same distance for the five compounds equal to 1,8 Å and dTi/Nb(1)-O(1) less than dTi/Nb(1)-O(1)', second octahedral Ti/Nb(2)O<sub>6</sub> more distorted, distances dTi/Nb(2)-O(2), dTi/Nb(2)-O(4) and dTi/Nb(2)-O(5) equals 2,0 Å. In this compounds studied (x = 0; 0,25; 0,5; 0,75 and 1) Ti and Nb cations show obvious off-center displacements along the c axis in both the Ti/Nb(1)O<sub>6</sub> and the Ti/Nb(2)O<sub>6</sub> octahedra. Besides, the unequal Ti/Nb(2)-O bonds length in the equatorial plane of Ti/Nb(2)O<sub>6</sub> octahedra indicates the displacement of the Ti/Nb(2) cations in the ab plane, and no displacement of the Ti/Nb(1) cations exists in the ab plane, which is obviously shown in the polyhedral representations along the c axis (Fig.7(a) and 7(b)). The insertion of neodymium into a square site leads to longer distances Ln-O, with dNd-O(3)=2,9230(7)Å and dNd-O(5)=2,7510(5)Å for the compound Sr<sub>2</sub>NdTi<sub>2</sub>Nb<sub>3</sub>O<sub>15</sub>; compared to the samarium compositions with dSm-O(3)=2,8245(1)Å and dSm-O(5)=2,6632(1)Å for Sr<sub>2</sub>SmTi<sub>2</sub>Nb<sub>3</sub>O<sub>15</sub>; in agreement with the ionic rays of these two lanthanides.

Table. 1: Confidence factors of the Rietveld refinement for the compositions Sr<sub>2</sub>Sm<sub>(1-x)</sub>Nd<sub>x</sub>Ti<sub>2</sub>Nb<sub>3</sub>O<sub>15</sub>

	x=0	x=0.25	x=0.5	x=0.75	x=1

The density measurement is carried out by the method of Archimedes. The measured value is close to the theoretical value for all compounds. The difference can exist at the theoretical value of the solid solution, because for  $x > 0$ , the density value is calculated by the values of the calculated mesh parameters.

### 3.4. Dielectric study

The Curie temperatures  $T_c$ , were determined by the variation of the real dielectric constant  $\epsilon_r$  as a function of the temperature, at the different frequencies from 100Hz to 1MHz. Fig 8. Gives the variation of the dielectric constant  $\epsilon_r$  as a function of temperature. The ferroelectric-paraelectric phase transition temperature does not change as the frequency increases.

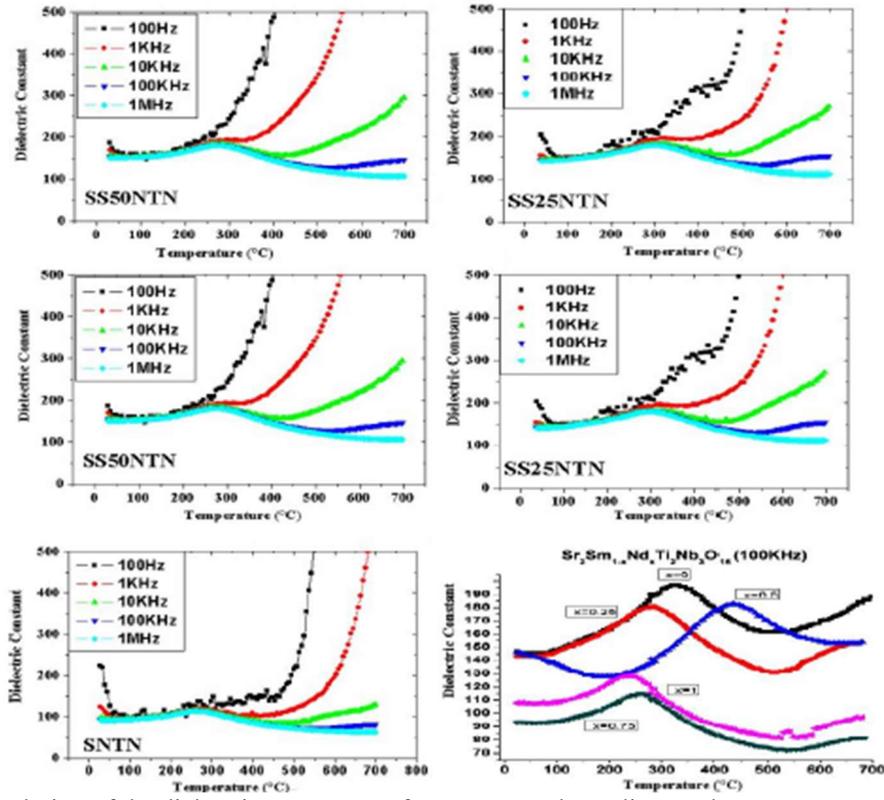

Fig. 8 : Thermal evolution of the dielectric constant  $\epsilon_r$  of  $SS_{(1-x)}N_xNT$  depending on the temperature at different frequencies: (a)  $x=0$ , (b)  $x=0.25$ , (c)  $x=0.5$ , (d)  $x=0.75$ , (e)  $x=1$ , and comparison of dielectric constant for  $x=0-1$  at 100 kHz.

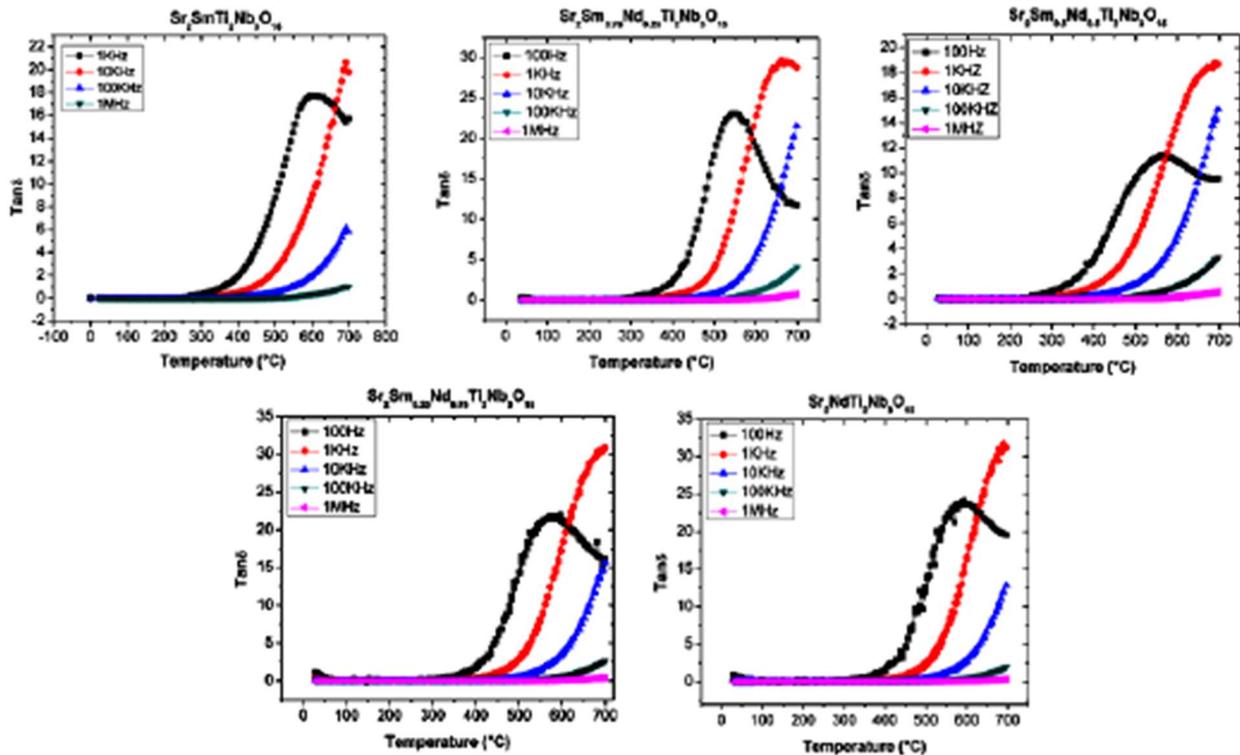

Fig. 9: Thermal evolution of the loss dielectric of  $Sr_2Sm_{1-x}Nd_xTi_2Nb_3O_{15}$

The phase transition temperature does not change when the frequency increases. The dielectric constant decreases with increasing frequency for all compounds. The dielectric of ceramics  $SS_{(1-x)}N_xNT$  at room temperature are shown in fig 10.

These ceramics have high dielectric constants  $\epsilon_r$  varies between 194 (100% Sm) and 127 (100% Nd) and a low dielectric loss of the order of  $10^{-4}$  at 1MHz.

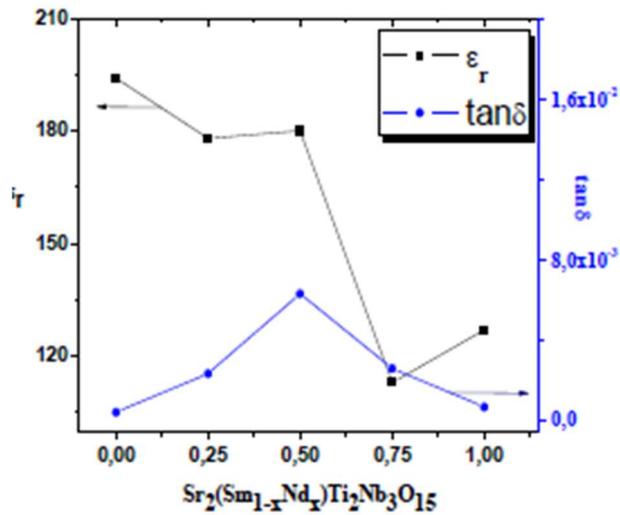

Fig. 10: Variation of  $\epsilon_r$  and  $\tan(\delta)$  with composition x.

The  $T_C$  value decreases as the size of the square-site cation increases that is when the samarium rate decreases. The Curie T temperature decreases from 332°C to 246°C (Fig.11). To verify the stoichiometry of our sintered pellets, we used X-ray energy dispersive spectroscopy (EDS) analysis. This technique has been used to ensure stoichiometry and to determine the possible presence of chemical elements in our ceramics. All the characteristic lines of our Sr, Sm, Nd, Nb, Ti and O chemical elements are present with varying rates depending on the chemical composition x. The EDS spectra presented in fig. 11 allowed us to assert the purity of our samples and at the same time to continue the evolution of the neodymium rate which should normally increase from the composition SSTN to SNTN.

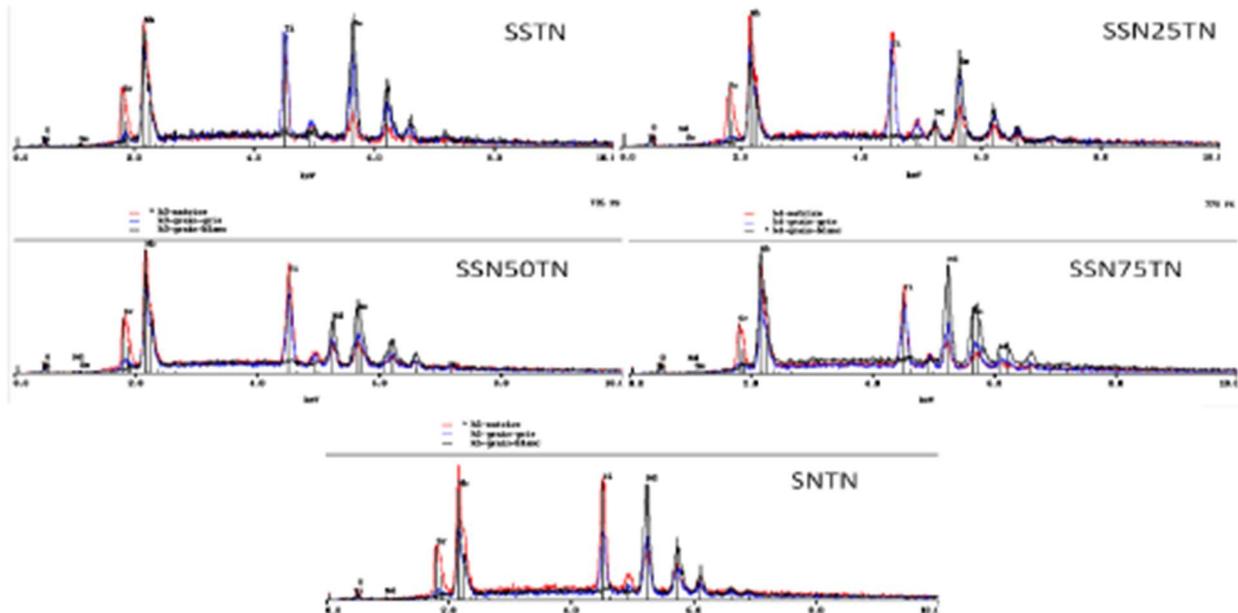

Fig. 11 : Analysis by EDS spectroscopy of the solid solution  $Sr_2Sm_{(1-x)}Nd_xTi_2Nb_3O_{15}$

After the thermal treatment of the images on the surface of the pellets of our samples, were taken by scanning electron microscopy (SEM), fig. 12. The SEM images show grain sizes of less than  $5\mu m$  with a good densification of the material, which seems homogeneous.

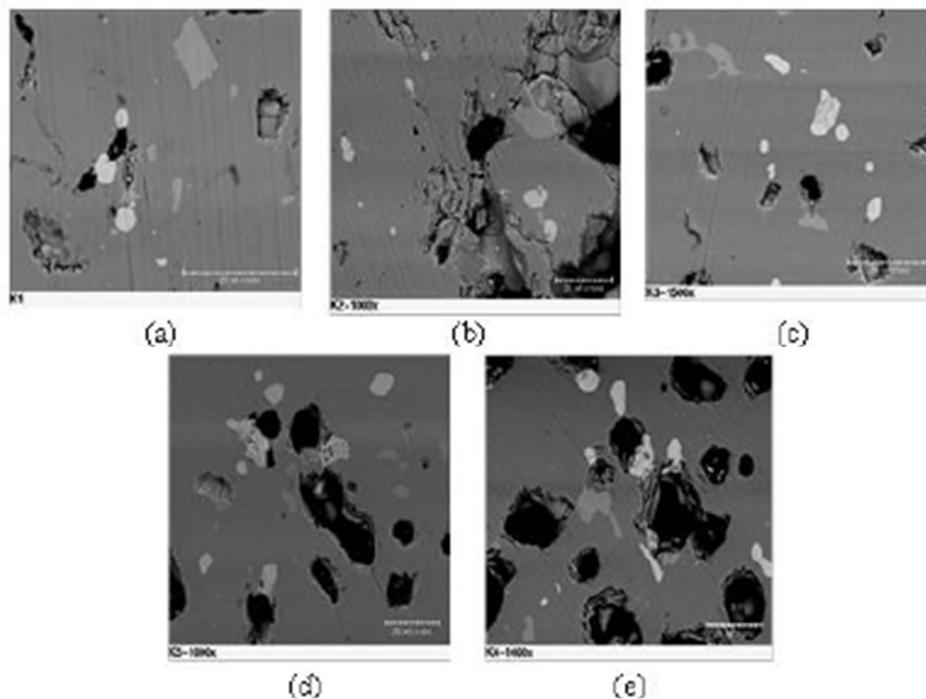

Fig. 12 : SEM analysis of the solid solution  $\text{Sr}_2\text{Sm}_{(1-x)}\text{Nd}_x\text{Ti}_2\text{Nb}_3\text{O}_{15}$  (a)=SSTN; (b)=SSN25TN; (c)=SSN50TN; (d)=SSN75TN and (e)=SNTN

#### 4. Conclusion

This work allowed us to synthesize new compositions of general formula  $\text{Sr}_2\text{Sm}_{(1-x)}\text{Nd}_x\text{Ti}_2\text{Nb}_3\text{O}_{15}$ ;  $x$  is between 0 and 1 belonging to the family of tetragonal bronzes of tungsten, was evidenced by reaction to the state solid. A structural study by XRD on powder has shown that the crystalline structure must be described in the quadratic system, space group  $P4bm$  and the parameters  $a=b \approx 12,2 \text{ \AA}$ ;  $c \approx 3,8 \text{ \AA}$ ;  $V \approx 579,0 \text{ \AA}^3$ ; space group is  $P4bm$ . The dielectric measurements have shown that synthesized compounds have dielectric constants  $\epsilon_r \geq 127$  are ferroelectric and have a phase transition which depends on the composition  $x$ . The results showed that the phase transition temperature  $T_c$  decreases gradually from 332 to  $246^\circ\text{C}$  as the  $\text{Sm}_{3+}$  level decreases in the structure.
